SQL Basics Cheat Sheet

AGGREGATION AND GROUPING

3ROUP BY groups together rows that have the same values in specified columns. t computes summaries (aggregates) for each unique combination of values.

AGGREGATE FUNCTIONS

- avg(expr) average value for rows within the group
- count(expr) count of values for rows within the group
 - max(expr) maximum value within the group
- min(expr) minimum value within the group
- sum(expr) sum of values within the group

EXAMPLE QUERIES

ind out the number of cities: SELECT COUNT(*) FROM city; Find out the number of cities with non-null ratings: SELECT COUNT(rating) FROM city; Find out the number of distinctive country values: SELECT COUNT(DISTINCT country_id) FROM city; SELECT MIN(population), MAX(population) FROM country;

Find out the smallest and the greatest country populations:

ind out the total population of cities in respective countries: SELECT country_id, SUM(population) 3ROUP BY country_id; FROM city

ind out the average rating for cities in respective countries if the average is above 3.0: SELECT country_id, AVG(rating) HAVING AVG(rating) > 3.0; GROUP BY country_id FROM city

A subquery is a query that is nested inside another query, or inside another subquery. There are different types of subqueries.

SINGLE VALUE

The simplest subquery returns exactly one column and exactly one row. It can be used with comparison operators =, <, <=, >, or >=.

This query finds cities with the same rating as Paris: SELECT name FROM city

```
WHERE name = 'Paris'
               SELECT rating
WHERE rating = (
                                  FROM city
```

MULTIPLE VALUES

A subquery can also return multiple columns or multiple rows. Such subqueries can be used with operators IN, EXISTS, ALL, or ANY

This query finds cities in countries that have a population above 20M: WHERE population > 20000000 SELECT country_id WHERE country id IN FROM country SELECT name

CORRELATED

A correlated subquery refers to the tables introduced in the outer query. A correlated subquery depends on the outer query. It cannot be run independently from the outer

This query finds cities with a population greater than the average population in the SELECT * country:

WHERE average_city.country_id = main_city.country_id FROM city average_city SELECT AVG(population) FROM city main_city WHERE population >

This query finds countries that have at least one city: WHERE country_id = country.id WHERE EXISTS (FROM city FROM country SELECT *

SET OPERATIONS

single result. The combined queries must return the same number of columns and compatible data types. The names of the corresponding columns can be different. Set operations are used to combine the results of two or more queries into a

SKATIN	iry id	П	2		:
		DE		Ч	•
	name	¥	9Z	_M	:
SYCLING	þŗ	1	7	m	:

H X

뭐 뭐 ~

UNION combines the results of two result sets and removes duplicates. UNION ALL doesn'tremove duplicate rows.

This query displays German cyclists together with German skaters:

WHERE country = 'DE'; WHERE country = 'DE' UNION / UNION ALL FROM skating FROM cycling SELECT name SELECT name

INTERSECT

INTERSECT returns only rows that appear in both result sets.

This query displays German cyclists who are also German skaters at the same time:

WHERE country = 'DE'; WHERE country FROM skating FROM cycling SELECT name INTERSECT

EXCEPT returns only the rows that appear in the first result set but do not appear in the second result set

This query displays German cyclists unless they are also German skaters at the same time:

WHERE country = EXCEPT / MINUS FROM skating FROM cycling SELECT name SELECT name

WHERE country = 'DE';
